LANGUAGES & TECHNOLOGIES

Languages: Java (21), C++ (11/23), Python.

Frameworks: Spring Boot, Spring Batch, Spring Cloud Gateway, Resilience4j

Distributed Systems: Apache Kafka (producers, consumers, consumer groups, DLT), event-driven architecture, microservices, idempotent processing

Databases & Caching: PostgreSQL, MongoDB, Redis (idempotency, session caching, rate limiting)

Observability: Prometheus, Grafana, Micrometer, Zipkin (distributed tracing)

Cloud & DevOps: AWS (EC2, SQS, Lambda), Docker, Docker Compose, Flyway, Linux, CI/CD

Reliability Patterns: Circuit breakers, exponential backoff retries, Outbox Pattern, dead-letter queues, backpressure, rate limiting

AI / LLM: RAG pipelines, LangChain, Hugging Face APIs; LLM-assisted development (Claude, Cursor)

EXPERIENCE

Backend Software Engineer · Xoriant **Technologies** · Pune, India

April 2024 – Present

Client: CLS Bank International · Globally distributed FX settlement platform

- Designed and implemented rule-driven, session-scoped currency rejection with full audit trails, enabling 6 of 18 production currencies to migrate to T+1 / same-day settlement and eliminating 1-2 days of settlement latency per cycle.
- Implemented SWIFT 2025-compliant message processing by evolving schemas and validation logic across SWIFT MFP/TDA channels, improving regulatory readiness and reducing settlement exceptions across affected currency pairs.
- Drove the migration of performance-critical C++11 modules to C++23 and refactored legacy components into AWS-hosted Java microservices, improving maintainability and deployment agility across the settlement pipeline.
- Sunsetting a discontinued legacy settlement module (~2,000 lines of code) that had accumulated dead coupling across service boundaries, reducing system complexity and eliminating a class of edge-case failures from the codebase.
- Diagnosed and resolved 2 Major-severity defects involving incorrect message-queue routing and strategy-pattern misparsing in multi-session scenarios, bugs that were silent under normal load but risked data consistency issues in concurrent UAT environments.
- Currently designing and building the technical solution for a new PVP session channel for faster settlement of select currencies, owning session state design, message routing, and integration with existing settlement workflows end-to-end.
- Provided L3 production ownership for mission-critical settlement systems, diagnosing live incidents and preserving settlement continuity during high-impact outages with documented root cause analysis.

PROJECTS

Distributed Payment Gateway | Java 21 · Spring Boot · Apache Kafka · PostgreSQL · Redis · Resilience4j · Prometheus · Grafana · AWS EC2 · Docker [GitHub](#)

- Designed and built a production-grade distributed payment processing platform from scratch, architecting 6 independent microservices (Payment, Mock Bank, Merchant, Webhook, Settlement, API Gateway) with strict service boundary separation, isolated databases, and asynchronous inter-service communication over Kafka.

- Implemented idempotent Kafka consumers with Dead Letter Topic (DLT) recovery, ensuring correct payment state transitions (PENDING to SUCCESS to SETTLED) under at-least-once delivery semantics and simulated consumer crash/restart scenarios.
- Engineered fault tolerance using Resilience4j: circuit breakers, retries with exponential backoff, time limiters, and per-merchant rate limiting via Spring Cloud Gateway, tested against bank timeout, UPI limit breach, CVV mismatch, and session expiry failure modes.
- Built webhook delivery infrastructure using the Transactional Outbox Pattern for guaranteed event publishing consistency between database commits and Kafka, with configurable retry queues for failed deliveries.
- Deployed the entire platform on AWS Free Tier EC2 using Docker Compose, self-hosting Kafka, PostgreSQL, Redis, Prometheus, and Grafana to simulate a production-grade fintech environment within real infrastructure constraints.
- Added full observability: distributed tracing with Micrometer and Zipkin across all services, and Prometheus/Grafana dashboards tracking payments/sec, p99 latency, Kafka consumer lag, and circuit breaker state.

Clone Catch: Personal Photo Organiser | Python · TensorFlow · VGG16 · Keras · KNN [GitHub](#)

- Built a personal tool to solve a real storage problem: too many near-duplicate and redundant photos accumulating across trips. The tool automatically identifies the sharpest, clearest version from groups of similar shots and discards lower-quality duplicates.
- Implemented face-based photo clustering using VGG16 embeddings and KNN similarity search: given 4-5 reference images of a person, the pipeline finds and groups all photos containing that individual into labelled folders, enabling clean per-person photo libraries at scale.
- Applied blur detection and facial clarity scoring using rule-based thresholds to rank images within duplicate clusters, achieving 90%+ clustering accuracy across personal test datasets.

CERTIFICATIONS

AWS Certified Developer – Associate · Amazon Web Services	2026
AWS Certified Cloud Practitioner · Amazon Web Services	2025
Oracle Certified Professional: Java SE 8 Developer · Oracle	2025
Oracle Cloud Infrastructure Developer Certified Associate · Oracle	2024

EDUCATION

B.E. Computer Science and Engineering: 8.6 GPA · KLE **Dr. M.S. Sheshgiri College of Engineering & Technology, VTU** 2020 – 2024

ACHIEVEMENTS

- XOR Champ 2025: Xoriant's company-wide performance award recognising outstanding delivery, ownership, and production impact on the FX settlement platform.
